

Experiment:

NFS Configuration in Linux

Aim

Configure a Network File System (NFS) server and access the shared directory from a client system.

Procedure

Step 1: System Preparation

Update the system and install required NFS packages.

Commands:

Step 2: Server Configuration

Create a directory to be shared and assign appropriate permissions.

Commands:

Create a sample file:

Step 3: Export Configuration

Open configuration file:

Write entry:

Apply configuration:

Step 4: Service Management

Start/restart NFS service:

Step 5: Client Configuration

Create mount point:

Mount shared directory:

Step 6: Verification

List contents:

Create file:

Verify on server:

Step 7: Analysis

1. Role of /etc/exports?
2. Why mounting is required?
3. Difference between local FS and NFS?
4. Effect of incorrect permissions?

Step 8: Advanced Task

Allow only specific IP and read-only access:

FAQ:

1. What is the role of /etc/exports?
2. Why is mounting required in NFS?
3. Difference between local file system and NFS.
4. What will happen if permissions are not set properly?
